

Hot Swappable 2-Wire Bus Buffer with Low Voltage Level Translation

FEATURES

- Level Translates 1V Signals to Standard 3.3V and 5V Logic Rails
- Allows Bus Pull-Up Voltages as Low as 1V on SDAIN and SCLIN
- Bidirectional Buffer* for SDA and SCL Lines Increases Fanout
- Prevents SDA and SCL Corruption During Live Board Insertion and Removal from Backplane
- Isolates Input SDA and SCL Line from Output
- 10kV Human Body Model ESD Protection
- Supports Clock Stretching, Arbitration and Synchronization
- High Impedance SDA, SCL Pins for $V_{CC} = 0V$
- \overline{CS} Gates Connection from Input to Output
- Compatible with I²C™, I²C Fast Mode and SMBus Standards (Up to 400kHz Operation)
- Small 8-Pin MSOP and DFN (3mm × 3mm) Packages

APPLICATIONS

- Hot Board Insertion
- Servers
- Capacitance Buffer/Bus Extender
- Desktop Computers

DESCRIPTION

The LTC® 4301L hot swappable, 2-wire bus buffer allows I/O card insertion into a live backplane without corruption of the data and clock busses. In addition, the LTC4301L SDAIN and SCLIN pins are compatible with systems with pull-up voltages as low as 1V. Control circuitry prevents the backplane from being connected to the card until a stop bit or a bus idle is present. When the connection is made, the LTC4301L provides bidirectional buffering, keeping the backplane and card capacitances isolated.

When driven low, the \overline{CS} input pin allows the part to connect after a stop bit or bus idle occurs. Driving \overline{CS} high breaks the connection between SCLIN and SCLOUT and between SDAIN and SDAOUT. A logic high on READY indicates that the backplane and card sides are connected together.

The LTC4301L is offered in 8-pin DFN (3mm × 3mm) and MSOP packages.

PIN FUNCTIONS

\overline{CS} (Pin 1): The connection sense pin is a 1.4V threshold digital input pin. For normal operation \overline{CS} is grounded. Driving \overline{CS} above the 1.4V threshold isolates SDAIN from SDAOUT and SCLIN from SCLOUT and asserts READY low.

SCLOUT (Pin 2): Serial Clock Output. Connect this pin to the SCL bus on the card.

SCLIN (Pin 3): Serial Clock Input. Connect this pin to SCL on the bus backplane.

GND (Pin 4, 9): Ground. Connect this pin to a ground plane for best results. Exposed pad (DFN package) is ground.

READY (Pin 5): The READY pin is an open drain N-channel MOSFET output which pulls down when \overline{CS} is high or when the start-up sequence described in the Operation section has not been completed. READY goes high when \overline{CS} is low and a start-up is complete.

SDAIN (Pin 6): Serial Data Input. Connect this pin to the SDA bus on the backplane.

SDAOUT (Pin 7): Serial Data Output. Connect this pin to the SDA bus on the card.

V_{CC} (Pin 8): Main Input Supply. Place a bypass capacitor of at least 0.01μF close to V_{CC} for best results.

The schematic diagram illustrates the internal architecture of the 43011B module. It features several key components and connections:

- Pin Connections:**
 - Pin 1:** CS (Chip Select), connected to a 1.4V source.
 - Pin 2:** SCLOUT (Serial Clock Output).
 - Pin 3:** SCLIN (Serial Clock Input).
 - Pin 4:** GND (Ground).
 - Pin 5:** READY (Ready signal), connected to a transistor and a pull-up resistor.
 - Pin 6:** SDAIN (Serial Data Input).
 - Pin 7:** SDAOUT (Serial Data Output).
 - Pin 8:** VCC (Supply Voltage).
- Internal Logic:**
 - PRECHARGE:** A block that controls the precharge circuitry, connected to the SDAOUT pin and the READY pin.
 - LOGIC:** A central logic block that receives inputs from CS, SCLIN, and SCLOUT, and outputs to the PRECHARGE block and the READY pin.
 - 95μs DELAY:** A delay block that provides a precise timing delay to the READY pin.
 - Transistors:** Several transistors are used for signal inversion and switching, including a large NPN transistor at the bottom right.
 - Resistors:** Resistors R1 and R2 (both 200k) are used for pull-up and pull-down functions.
- Signal Flow:**
 - The CS signal is inverted and connected to the 1.4V source.
 - The SCLIN signal is connected to the SCLOUT pin and the LOGIC block.
 - The SDAOUT pin is connected to the PRECHARGE block and the READY pin.
 - The READY pin is connected to the LOGIC block and the 95μs DELAY block.

OPERATION

Start-Up

When the LTC4301L first receives power on its V_{CC} pin, either during power-up or live insertion, it starts in an undervoltage lockout (UVLO) state, ignoring any activity on the SDA or SCL pins until V_{CC} rises above 2.5V. This is to ensure that the part does not try to function until it has enough voltage to do so.

During this time, the 1V precharge circuitry is active and forces 1V through 200k nominal resistors to the SDAOUT and SCLOUT pins. Precharging the SCLOUT and SDAOUT pins to 1V minimizes the worst-case voltage differential these pins will see at the moment of connection, therefore minimizing bus disturbances.

Once the LTC4301L comes out of UVLO, it assumes that SDAIN and SCLIN have been inserted into a live system and that SDAOUT and SCLOUT are being powered up at the same time as itself. Therefore, it looks for either a stop bit or bus idle condition on the backplane side to indicate the completion of a data transaction. When either one occurs, the part also verifies that both the SDAOUT and SCLOUT voltages are high. When all of these conditions are met, the input-to-output connection circuitry is activated, joining the SDA and SCL busses on the I/O card with those on the backplane.

Connection Circuitry

Once the connection circuitry is activated, the functionality of the SDAIN and SDAOUT pins is identical. A low forced on either pin at any time results in both pin voltages being low. For proper operation, logic low input voltages should be no higher than 0.4V with respect to the ground pin voltage of the LTC4301L. SDAIN and SDAOUT enter a logic high state only when all devices on both SDAIN and SDAOUT release high. The same is true for SCLIN and SCLOUT. This important feature ensures that clock stretching, clock synchronization, arbitration and the acknowledge protocol always work, regardless of how the devices in the system are tied to the LTC4301L.

Another key feature of the connection circuitry is that it provides bidirectional buffering, keeping the backplane and card capacitances isolated. Because of this isolation, the waveforms on the backplane busses look slightly different than the corresponding card bus waveforms as described here.

Input-to-Output Offset Voltage

When a logic low voltage, V_{LOW1} , is driven on any of the LTC4301L's data or clock pins, the LTC4301L regulates the voltage on the other side of the device (call it V_{LOW2}) at a slightly higher voltage, as directed by the following equation:

$$V_{LOW2} = V_{LOW1} + 75\text{mV} + (V_{CC}/R) \cdot 70\Omega \text{ (typical)}$$

where R is the bus pull-up resistance in ohms. For example, if a device is forcing SDAOUT to 10mV where $V_{CC} = 3.3\text{V}$ and the pull-up resistor R on SDAIN is 10k, then the voltage on SDAIN = $10\text{mV} + 75\text{mV} + (3.3/10000) \cdot 70 = 108\text{mV}$ (typical). See the Typical Performance Characteristics section for curves showing the offset voltage as a function of V_{CC} and R.

Propagation Delays

During a rising edge, the rise time on each side is determined by the bus pull-up resistor and the equivalent capacitance on the line. In Figure 1, $V_{CC} = 3.3\text{V}$, SDAOUT and SCLOUT are pulled-up to 3.3V with 10k resistor (20pF on this side) and SDAIN and SCLIN are pulled-up to 1.2V with a 2k resistor (55pF on this side). Lower pull-up resistor values are used on the input side to allow the output side to be released sooner.

Figure 1. Input-Output Connection

There is a finite high to low propagation delay through the connection circuitry for falling waveforms. Figure 2 shows the falling edge waveforms for the same pull-up resistors and equivalent capacitance conditions as used in Figure 1. An external N-channel MOSFET device pulls down the voltage on the side with 55pF capacitance; LTC4301L pulls down the voltage on the opposite side with a delay of 60ns.

OPERATION

This delay is always positive and is a function of supply voltage, temperature and the pull-up resistors and equivalent bus capacitances on both sides of the bus. The Typical Performance Characteristics section shows the high to low propagation delay as a function of temperature and voltage for 10k pull-up resistors pulled-up to V_{CC} and 100pF equivalent capacitance on both sides of the part. Larger output capacitances translate to longer delays (up to 150ns). Users must quantify the difference in propaga-

Figure 2. Input-Output Connection
High to Low Propagation Delay

tion times for a rising edge versus a falling edge in their systems and adjust setup and hold times accordingly.

Ready Digital Output

This pin provides a digital flag which is low when either \overline{CS} is high or the start-up sequence described earlier in this section has not been completed. READY goes high when \overline{CS} is low and start-up is complete. The pin is driven by an open-drain pull-down capable of sinking 3mA while holding 0.4V on the pin. Connect a resistor of 10k to V_{CC} to provide the pull-up.

Connection Sense

When the \overline{CS} pin is driven above 1.4V with respect to the LTC4301L's ground, the backplane side is disconnected from the card side and the READY pin is internally pulled low. When the pin voltage is low, the part waits for data transactions on both the backplane and card sides to be complete (as described in the Start-Up section) before reconnecting the two sides. At this time the internal pulldown on READY releases.

APPLICATIONS INFORMATION

Live Insertion and Capacitance Buffering Application

Figure 3 illustrates applications of the LTC4301L with different bus pull-up and V_{CC} voltages, demonstrating its ability to recognize and buffer bus data levels that are above or below its V_{CC} supply. All of these applications take advantage of the LTC4301L's Hot Swap™ controlling, capacitance buffering and precharge features. If the I/O cards were plugged directly into the backplane without the LTC4301L buffer, all of the backplane and card capacitances would add directly together, making rise- and fall-time requirements difficult to meet. Placing an LTC4301L on the edge of each card, however, isolates the card capacitance from the backplane. For a given I/O card, the LTC4301L drives the capacitance of everything on the card and the backplane must drive only the capacitance of the LTC4301L, which is less than 10pF.

In most applications the LTC4301L will be used with a staggered connector where V_{CC} and GND will be long pins. SDA and SCL are medium length pins to ensure that the V_{CC} and GND pins make contact first. This will allow the precharge circuitry to be activated on SDA and SCL before they make contact. \overline{CS} is a short pin that is pulled up when not connected. This is to ensure that the connection between the backplane and the cards data and clock busses is not enabled until the transients associated with live insertion have settled.

Figure 4 shows the LTC4301L in an application where all of the pins have the same length. In this case, an RC filter circuit on the I/O card with a product of 10ms provides a filter to prevent the LTC4301L from becoming activated until the transients associated with live insertion have settled. Connect the capacitor between V_{CC} and \overline{CS} , and the resistor from \overline{CS} to GND.
